## INTRODUCTION

The Narva–Luga interfluvium, named after the two major rivers in the Estonian–Russian border area, is located on the south-eastern coast of the Gulf of Finland of the Baltic Sea (Fig. 1A & B). It consists of two large landscape regions: the coastal lowland in the north and the plateau (the Baltic Klint) in the south. The lowland, characterised by marine and fluvial sediments, is geologically an old Klint bay and sharply contoured to the south and east by the Cambrian/Ordovician Baltic Klint. The lowland is located in a sensitive coastal area, which has experienced a slow but uneven interplay of glacioisostatic land-uplift and eustatic changes of sea level. As a result, transgressions and regressions of the Baltic Sea have affected and reshaped the area several times in the past (for a detailed hydrological and geological history, see Rosentau *et al.* 2013).

Although a couple of stone axes had been discovered in the region already during the second half of the 19th century (Tallgren 1922, 54), substantial Stone and Bronze Age research began only in the 1930s with excavations conducted by Richard Indreko (1932; 1948). In the 1950s and 1960s several new sites were found and large-scale excavations, led by Nina Nikolaevna Gurina and Lembit Jaanits, were carried out at some of them (Jaanits 1955; 1965; Gurina 1967; for a detailed research history until 1995, see Kriiska 1996). During these

fieldwork campaigns the first Corded Ware period materials were unearthed at the settlement sites Riigiküla I and II, as well as at Narva Joaorg (Jaanits 1966).

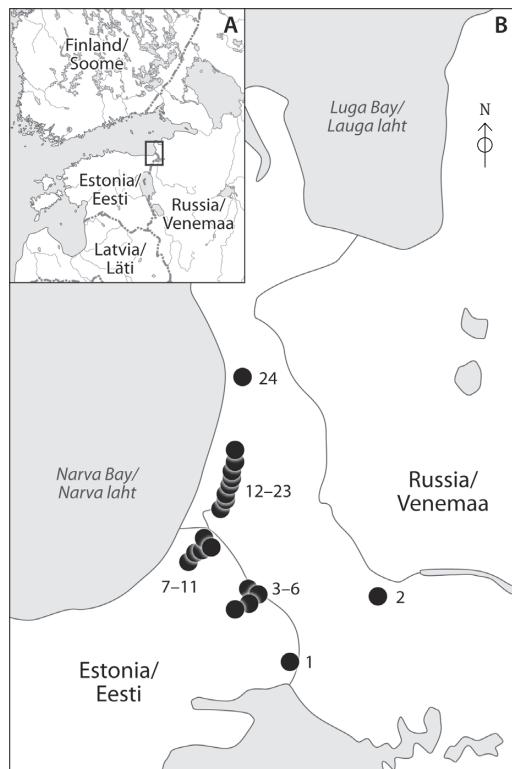

The second phase of intensive research on the Estonian side of the Narva–Luga interfluve started in the 1990s, when numerous sites were discovered and excavated, including two Corded Ware settlements (Riigiküla IV and XIV) (Kriiska 2000; Kriiska & Nordqvist 2007). Ten years ago (2005) research was further intensified, as the studies started anew also on the Russian side of the interfluve. Since then research has been conducted in the Narva–Luga interfluve annually by an international crew of archaeologists and natural scientists (geologists, marine geologists, limnologists, palaeogeographers, geomorphologists, geochemists, palynologists, geophysicists and other specialists), mainly from Tartu and St. Petersburg.

A brief overview of the main results of the investigations at the Corded Ware sites in the Narva–Luga interfluve between 2008 and 2014 will be given in this article. The results presented here are an updated version of a parallel paper published in Russian (Kriiska *et al.* 2015).

## RESEARCH OF CORDED WARE SITES IN 2008–2014

As a result of recent fieldwork, over 40 new sites have been discovered, which date between 5100–2000 cal BC (partly published in Gerasimov *et al.* 2012; 2013). The results show that the Narva–Luga region was densely inhabited at least throughout the later part of the Stone Age. In addition, the finds have given important insights into the local landscape and hydrological development (see Rosentau *et al.* 2013; Gerasimov *et al.* 2014).

The recent discoveries include altogether 19 Corded Ware settlement sites and one cemetery (partly published in Kriiska & Nordqvist 2010; 2012; Gerasimov *et al.* 2012; 2013; Kriiska *et al.* 2015) (Table 1). The sites are  $^{14}\text{C}$ -dated to ca. 2800–2000 cal BC (Table 2). The total number of Corded Ware sites – including the previously found locations – is 24 in this very small area (only ca. 1000 km<sup>2</sup>) (Fig. 1B). This concentration can be held significant considering that in the vast region between the Kaliningrad oblast and Finland altogether ca. 500 settlement sites and ca. 80 cemeteries are known (Nordqvist *et al.* subm.).

## SITES, FINDS, AND DATINGS

The investigated Corded Ware settlement sites are diverse in terms of their location, as well as in their areal extent, thickness and intensity of cultural layer, and numbers of finds. Even if many of the sites are small and fairly compact, the sites in the Narva–Luga area seem to be somewhat larger and have more finds than the average Corded Ware sites in the eastern Baltic Sea region (cf. e.g. Jaanits 1966, 61–63; Kriiska 2000, 70; Girininkas 2002, 92). In the most extreme cases (Narva-Jõesuu IIb, and the previously-discovered and -studied Riigiküla XIV) the sites are more than half a hectare in area, and in Rosson region, where extensive territories have been opened by ploughing a large logging area, the sizes of sites (i.e. surface collected find areas) vary between 80 m<sup>2</sup> and 4600 m<sup>2</sup> (Fig. 2).

The maximum thickness of cultural layers at settlement sites is usually max. 20–30 cm, although in some rare cases deposits of over 1.5 m have been encountered. The latter are connected to the two semi-subterranean pithouses found at the site Narva-Jõesuu IIb. Both rectangular-shaped dwellings had been dug to the depth of almost one metre into the ground. Charcoal-rich zones observed by the walls of the structures suggest that the buildings had been founded on timber frames (Fig. 3). The sizes of the buildings are not yet totally clarified, but the walls have been at least 3–4 m long. A fireplace was found inside one of the pithouses.

The composition of find material from the settlement sites is relatively uniform. The assemblages consist mostly of pottery fragments, although in some cases quartz and flint flakes and artefacts, as well as a few whetstones have been found (Kriiska 2000, 63; Kriiska & Nordqvist 2007, 33–34) (Table 1). A fragment of a battle axe, found at the site Rosson 9, can be considered an exception. It is, of course, difficult to link the lithic material securely to Corded Ware if the contexts are

mixed and contain several temporal components, albeit at least at Riigiküla XIV and Narva-Jõesuu IIb the artefacts have been found in solid, non-mixed contexts.

Corded Ware pottery sherds (partly published in Kriiska 1996, 64–69; Kriiska & Nordqvist 2007, 34–35; 2010, 20; Kriiska & Rappu 2008, 21; Gerasimov *et al.* 2013, 24; Kriiska *et al.* 2015) originate mostly from flat-bottomed pots (Fig. 4: 2–6), and only rarely from beakers (Fig. 4: 1). The pots are usually made of clay tempered with organic (crushed plant) admixtures, and seldom with mineral material (rock debris, sand, and grog). Also vessels tempered with combinations of organic and mineral admixtures are known. The beakers are generally mineral-tempered. The vessels are shaped by coiling technique and have N-type conjunctions. The pot surfaces are either smoothed (Fig. 4: 1, 6) or striated (Fig. 4: 2–5), and have often fibre-impressions on them. Decorative elements – pits, notches, cord impressions, grooves – are located only on the upper parts of the vessels, mostly at the neck and rim. Textile impression is encountered rarely on some of the vessels.

Currently, only six radiocarbon dates exist from five sites (Table 2). According to AMS dates of burned animal bones, the site Narva-Jõesuu IIb was used at least around 2800 cal BC and 2200 cal BC. Dated crusts on a Corded Ware sherd from Narva-Jõesuu IIa gave a median age of about 2400 cal BC. A burned animal bone from Rosson 1a was dated to *ca.* 2200 cal BC. According to the  $\delta^{13}\text{C}$  values (Narva-Jõesuu IIa -30.5 ‰ and Rosson 1a -28.2 ‰) the last two dates may be affected by reservoir effect and give therefore too old ages, even if they are fairly young for Corded Ware datings as such. Nevertheless, the youngest Corded Ware date comes

**Fig. 4.** Corded Ware pottery found from settlements in the Narva–Luga area:

1 – Rosson 8, 2 – Rosson 7, 3–6 – Narva-Jõesuu IIb.

**Jn 4.** Nõörkeraamika killud Narva – Lauga piirkonnast: 1 – Rosson 8, 2 – Rosson 7, 3–6 – Narva-Jõesuu IIb.  
Photos / Fotod: Aivar Kriiska

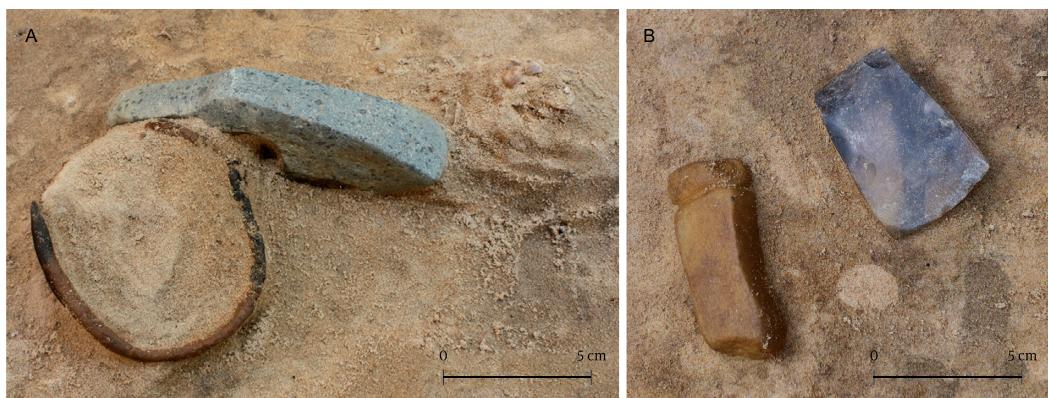

from the site Väike-Ropsu 1, with a median age of about 2000 cal BC. Thus, the datings from the Narva–Luga interfluvе basically cover the whole period of time proposed for Corded Ware in the eastern Baltic Sea region, although they also indicate quite late survival of Corded Ware in this area. Nevertheless, the data is too patchy for determining any internal chronologies or, for instance, temporal differences in pottery.

With regards to the Corded Ware settlement pattern, two major variants for locating the sites can be distinguished in the Narva–Luga interfluvе. The presence or absence of a water-course or a waterbody near the settlement acts here as the separating factor. Several sites are located on the banks of large rivers, like River Narva (Riigiküla I and II, Narva Joaorg), or on the banks of smaller streams (Lommi I and possibly Narva-Jõesuu I, IIa, IIb, III and IV). Numerous sites lay also near small ponds (Rosson 1–10). However, there are also sites like Väike-Ropsu 1, which are situated on sandy ridges far away from ancient or present-day waterbodies.

### THE FIRST CORDED WARE BURIALS IN THE NARVA–LUGA INTERFLUVЕ

At the site Narva-Jõesuu IIb two graves from the Corded Ware period have been discovered. They are located just a few metres apart, and both are oriented in the north-east–south-west direction. The graves are *ca.* 2 m long, 0.5–1 m wide, and dug into the depth of *ca.* 1.2–1.4 m (from the present-day soil surface). The human remains have decayed completely, but the presence of grave goods confirms the interpretation of these features as graves.

The first grave can be assumed to have been a double burial based on the existence of two sets of grave goods in it (further, the remains of the teeth of an infant were encountered in this grave). One of the deceased was equipped with a battle axe, a whetstone, a Corded Ware beaker and a possible (i.e. fragmented) amber pendant, and the other one (the infant) with a battle axe, a Corded Ware beaker and another small ceramic vessel (Fig. 5A). The second grave contained most likely only one person with grave goods consisting of a Corded Ware beaker, a four-sided adze made of flint and a whetstone (Fig. 5B).

**Fig. 5.** Narva-Jõesuu IIb, a battle axe and a small ceramic vessel discovered from the double-burial in 2013 (A), and a four-sided flint adze and a whetstone found in the burial studied in 2014 (B).

## DISCUSSION AND CONCLUSIONS

The recently-found and -investigated Corded Ware sites and graves in the Narva–Luga interfluve substantially expand our knowledge of the period, and also provide supporting – as well as contradicting – evidence for several existing ideas and views. Most of the previously-known Corded Ware settlement sites and assemblages in Estonia and in the eastern part of the Baltic Sea area are mixed with older and/or younger archaeological material (Kriiska 1996, 70). However, in the Narva–Luga area there is a unique possibility to investigate sites without or with very little artefacts from other prehistoric periods.

The find materials from settlement sites are relatively uniform, and characterized by a fairly modest amount of lithic material. This is in accordance with observations made at other sites around the Baltic Sea (Jaanits 1966, 61–63; Edgren 1970, 39–42; Girininkas 2002, 92). The excavations at Riigiküla and Narva-Jõesuu sites, as well as finds collected on the open soil surface in the Rosson region, show that the lack of lithic materials is a real phenomenon, and not just a result of insufficient investigations or limited excavations (Table 1). This may be due to various reasons, including the replacement of stone with other (organic) raw materials. The bone and antler objects (awl, knives, chisels, fish spears, fasteners of garments) from Estonian Corded Ware graves (Lõugas *et al.* 2007, table 2) confirm the big diversity in the usage of non-lithic artefacts. Unfortunately, bone and antler tools are rarely found at settlement sites and even then they are very poorly preserved – in many areas organic artefacts have not preserved at all. The second factor possibly explaining the limited use of flint and quartz implements could be the replacement of different artefact types by multifunctional flint knives. Such knives, made from long flint blades, are typical artefacts of the period and a very common find from Corded Ware graves in Estonia (Kriiska & Tvauri 2002, 81). Nevertheless, they are practically absent in the Narva–Luga area. Despite the small size of lithic assemblages, some knowledge has also been obtained of the lithic technology of Corded Ware people, which included at least the use of bipolar knapping technique (Kriiska & Nordqvist 2007, 34).

The pottery found in the Narva–Luga area, at least based on our current state of knowledge and regardless of absolute dates, seems to be very similar throughout the whole region. Organic admixtures in clay, fibre-impressions on the surfaces, as well as the shape of the vessels, connect it closely also with the neighbouring areas. The similarities in pottery provide even a possibility to distinguish a separate Corded Ware cultural area in Estonia, Latvia, Ingria and Karelian Isthmus (Russia) and south-eastern Finland. However, the details of, and reasons behind this development still need further clarification and research.

The remains of the two semi-subterranean pithouses found at the site Narva-Jõesuu IIb are fairly unique in the sphere of the Corded Ware phenomenon around the Baltic Sea. Thus far, no constructions have been unearthed in the neighbouring regions that could be unequivocally recognized as remains of houses. The closest possible building remains are known at the site Valma in central Estonia, where four stone hearths, found in pairs and located four to five metres apart, have been interpreted to mark the location of two parallel longhouses (Jaanits *et al.* 1982, 105–106). In southern Finland, at the settlement site of Malmbäcken, two 4 m long and more than 1 m deep, narrow and oval depressions filled with cultural soil have been proposed to represent ‘dwelling pits’ (see Edgren 1970, 40–41). However, this interpretation is not convincing, and apparently the pits do not represent Corded Ware dwellings. Also the connection between the few Corded Ware period finds and the multi-room pithouse studied at the Meskäärtty site in south-east Finland (Mökkönen 2008) remains

thus far unproven. The nearest clear remains of Corded Ware houses are known in Sweden and, if the so-called Rzucewo culture is also included within the Corded Ware phenomenon, in the south-eastern coast of the Baltic Sea – in Poland, Kaliningrad oblast and Lithuania. Like the house remains of Narva-Jõesuu IIb, also some of the Rzucewo and Swedish Battle Axe dwellings were semi-subterranean, although shallower and built using post- and wattle-and-daub structures (Rimantienė 1989, 29; Larsson 2009; Zal'tzman 2010, 30–41). According to our knowledge, the timber frames encountered at Narva-Jõesuu IIb find the only direct parallels among the antiquities of Balanovo group in the Vyatka and Oka River Basins of central Russia (Bader & Khalikov 1987, 78).

The location of Corded Ware sites in the Narva–Luga interfluvium – as elsewhere – differs from the location of sites of earlier periods. The natural conditions in the area, of course, had also changed by the Corded Ware period. During the regression of the Litorina Sea, large semi-closed lagoons were isolated from the sea by sandy spits, and also small islands were formed in the Narva–Luga area. From the end of the 6th millennium cal BC onwards groups manufacturing Narva-type pottery, and from the beginning of the 4th millennium cal BC Comb Ware pottery, customarily established their settlements on the shores of these spits and lagoons (Kriiska 1999, 174; Rosentau *et al.* 2013, fig. 7: E–F). Over time the lagoons became totally isolated from the sea and gradually overgrew, and by the appearance of Corded Ware, the 3rd millennium cal BC, the landscape in the region was probably relatively similar to the present, comprising of sandy ridges alternating with rivers, small lakes, ponds and bogs (Rosentau *et al.* 2013, fig. 7: I). As stated above, during this time settlements were located on the banks of rivers and by the ponds, and no sites can be found along the sea shore.

However, changes in the Corded Ware settlement pattern cannot only be explained by changes in the natural environment. The changing settlement pattern seems to be a general tendency, as the coastal sites decrease and even disappear in all coastal areas of the eastern part of the Baltic Sea (Kriiska 2000, 71–72; Edgren 1984, 75; see also Mökkönen 2011 for inland examples). Most likely, the changes reflect modifications in the general mode of living, as well as in the subsistence. Despite the fact that Estonian Corded Ware burials include bones of domestic animals (sheep/goat, pig and bovine) (Lõugas *et al.* 2007), that *Cerealia* type pollens (barley and wheat) are recognized in Estonian bog and lake sediments of this time (Kriiska 2009 with references), and that there is even an imprint of a barley grain on a Corded Ware vessel from northern Estonia (Lang 1996, 165, 168–169), farming is not visible in the archaeological material collected from the Narva–Luga region and, unfortunately, high-resolution pollen analyses are not completed so far. Only some freshwater fish bones (pike, perch, and carp) and some tubular bird bones (Kriiska 2000, 74) have been recognized in the extremely fragmented assemblages of burned bones, albeit most of the osteological material is not yet analysed. Hopefully the ongoing archaeozoological and macrofossil analyses from the cultural deposits of Narva-Jõesuu IIb, as well as the analyses of pollen samples cored from ponds next to the Rosson sites will provide new material and information about the subsistence and economy of Corded Ware groups of this area.

Like in much of the eastern Baltic Sea area, Corded Ware settlement sites in the Narva–Luga interfluvium are usually small and have relatively thin cultural layers and scanty finds. Such sites seem to indicate that single family households were the basic unit of settlement (Lang 1996, 444; Kriiska 2000, 74). At the same time, sites like Riigiküla XIV, Rosson 9 and Narva-Jõesuu IIb show that also large sites, rich in finds and with thick cultural layer exist: at Riigiküla XIV test pitting revealed three large, individual activity areas and in Narva-Jõesuu IIb

the presence of at least two houses is confirmed. As the existing  $^{14}\text{C}$ -dates from Narva-Jõesuu IIb propose different use periods for different parts of the site, not all of the territory of the site was necessarily occupied simultaneously, and, consequently, the structures observed there may not be contemporary (the same applies to the activity areas at Riigiküla XIV and Rosson 9). Still, much more work and datings are needed to solve these questions.

Only one Corded Ware cemetery is currently known in the Narva–Luga region. Nevertheless, the burials at Narva-Jõesuu IIb exhibit special characteristics that differ from the other Estonian Corded Ware burials. The battle axes found in the double burial represent types not common in the eastern Baltic Sea area. On morphological grounds they have the best parallels in the Fatyanovo area of the Volga–Oka interfluvium in central Russia (Raushenbakh 1960, 54–55; Krajnov 1972, fig. 22–23). Before these finds, only a few examples of Fatyanovo axes were known in Estonia, of which one was even found in Narva area (Äyräpää 1952, 89), four axes were known in Finland and three axes on Karelian Isthmus (Nordqvist & Hääkälä 2014, table 1). The small, oval bowl-like vessel found in the double burial is likewise a unique find in Estonian context. Good analogies also for this find can be found in the Fatyanovo material (Krajnov 1972, fig. 42; 1987, fig. 31). However, what kind of relationships these new finds indicate between the research area and the Fatyanovo region is a topic for more comprehensive studies in the future.

## ACKNOWLEDGEMENTS

This paper has been supported by the research projects of the Estonian Research Council ‘The reflections of the Eurasian Stone and Bronze Age social networks in the archaeological material of the Eastern Baltic’ and ‘Estonia in Circum-Baltic space: archaeology of economic, social, and cultural processes’; the European Union through the Centre of Excellence in Cultural Theory at the University of Tartu; Museum of Anthropology and Ethnography named after Peter the Great, Kunstkamera / Russian Academy of Sciences; the research project ‘The last pioneers of Europe: formation of social-cultural units in the Gulf of Finland region in Early and Middle Holocene environmental changes’ funded by the Russian Foundation for Basic Research, project 15-06-05548; the research project ‘The use of materials and the Neolithisation of north-east Europe (c 6000–1000 BC)’ funded by the Academy of Finland / University of Oulu; and OÜ Arheograator. Authors also thank Kristel Roog for preparing the illustrations, as well as everyone who has participated in the fieldwork.

## EESTI JA VENEMAA PIIRIALAL NARVA – LAUGA JÕGEDE VAHELISES PIIRKONNAS AASTATEL 2008–2014 TEOSTATUD NÖÖRKERAAMIKA MUISTISTE UURIMISE ESIALGSEID TULEMUSI

Aivar Kriiska, Kerkko Nordqvist, Dmitriy V. Gerasimov ja Sarita Sandell

Narva – Lauga jõgedevahe asetseb Eesti ja Venemaa piirialal Läänemere kagurannikul (jn 1). See hõlmab kahte maastikuregiooni – omaaegses klindilahes paiknevat rannikumadalikku ja lavamaad. Tegemist on nii iso- kui ka eustaatilistest protsessidest tugevasti mõjutatud rannikupiirkonnaga, kus on jälgitavad kiviajal Läänemere nõos paiknenud veekogu nii transgressiivsed kui ka regressiivsed staadiumid.

Nõörkeraamika komplekside uurimine algas piirkonnas 1950. aastatel Nina Gurina ja Lembit Jaanitsa välja-kaevamistega Riigiküla (I ja II) ja Narva Joaoru asulakohtadel. Uus etapp algas 1990. aastatel, mil leiti ja uuriti kahte Riigikülas paiknevad nõörkeraamika asulakohta (Riigiküla IV ja XIV). Kümme aastat tagasi (2005) alustati intensiivsemaid uuringuid ka Venemaa poolel ja sellest ajast alates on toiminud Narva – Lauga piirkonnas igal välitööde hooajal ühisid rahvusvahelised ja interdistsiplinaarsed urimistööd. Aastatel 2008–2014 aset leidnud välitööde käigus on avastatud u 1000 km<sup>2</sup> suuruselt alalt üle 40 uue kinnismuistise dateeringuga 5100–2000 eKr,

sh 19 nöörkeraamika kompleksi asulakohta ja üks matmispai. Alates 2008. aastast on üheks fookuseks olnud nöörkeraamika kompleksi asula- ja matmiskohad.

Uurimispiirkonna nöörkeraamika kompleksi asulakohtade paiknemises on näha mitu erinevat süsteemi. Need võivad asetseda (1) suure Narva jõe (Riigiküla I and II, Narva Joaorg) ja (2) väikejõgede (Lommi I ning arvatavasti Narva-Jõesuu I, IIa, IIb, III ja IV) kallastel, (3) väikeste järvikute kallastel (Rosson 1–10) või (4) kohtades (Väike-Ropsu 1) mille läheduses ei ole vähemalt tänapäevani säilinud veekogu.

Asulakohad on erineva suurusega. Rossoni asulakohad, mis on avatud ulatuslikule metsapõlengule järgne-nud künniga ja nii hästi dokumenteeritavad, on suuruses  $80 \text{ m}^2$  kuni  $4600 \text{ m}^2$  (jn 2). Narva-Jõesuu IIb ja Riigiküla XIV asulakohas lasub kultuurkiht aga isegi üle poole hektari suurusel alal. Kultuurkihi paksus on üldjuhul maksimaalselt 20–30 cm, erandina Narva-Jõesuu IIb süvendpõhjaliste hoonete alal isegi üle 1,5 m. Need kaks osaliselt uuritud hoonejääanust olid nelinurkse kujuga ja ehitatud rõhtpalkidest (jn 3). Ehitiste mõõtmed ei ole selged, kuid seinad on olnud algsest vähemalt 3–4 m pikkused. Ühest elamujääanusest kaevati välja ka kivideta tulease.

Asulakohtade leiumaterjal on suhteliselt ühekülgne, peamiselt savinõukillud ning vähesed kvarts ja tulekivi killud ja neist valmistatud esemed, mõned lihvimiskivid ja erandina silmaga kivikirve katke Rosson 9 asulakohalt (tabel 1). Savinõukillud pärinevad lamedapõhjalistest pottidest, mõnel juhul ka peekritest (jn 4). Nõud on enamasti valmistatud orgaanilise (purustatud taimed, harvem mineraalse (kivipurd, liiv, šamott) või kombineeritud lisandiga segatud savist linnitehnikas (N-tüüpi ühenduspinnad). Pinnad on silutud või riibitud. Ornamentelementidest esineb lohke, täkked, nöörivajutisi ja sooni, mis paiknevad üldjuhul vaid nõu ülaosas – kaelal või serval. Esineb ka tekstiilijäljendi kaetud kilde.

Praeguseks on tehtud kuus radiosüsiniku dateeringut viiest asulakohast (tabel 2), kusjuures osa neist on arvatavasti reservuaarefekti tõttu andnud tegelikkusest vanema tulemuse. Usaldusvärsed vanusemäärangeud jäädvad keskmistatult vahemikku 2800–2000 eKr, mis osutab nöörkeraamika kompleksi nii suhteliselt varasele algusele kui hilisele lõpule Narva – Lauga piirkonnas.

Narva-Jõesuu IIb asulakohast on välja kaevatud kaks nöörkeraamika kompleksi hauda. Need asetsevad vaid mõne meetri kaugusele teineteisest ja mõlemad on orienteeritud kirde–kagu-suunaliselt. Hauad on u 2 m pikkused ja 0,5–1 m laiused ning haudade põhi tänapäevases maapinnast 1,2–1,4 m sügavusel. Inimsäilmed on peaaegu täielikult kõdunenud, kuid leukogumid ei jäta kahtlust, et tegemist on haudadega. Otsustades kahe leukogumi põhjal, oli ühte hauda maetud kaks inimest. Ühele neist oli kaasa pandud venekirves, lihvimiskivi, nöörkeraamiline peeker ja arvatavasti merevaigust ripats; teisele venekirves, nöörkeraamiline peeker ja väike savinõu (jn 5A). Teise hauda oli tõenäoliselt maetud üks inimene, kaasas nöörkeraamiline peeker, neljatahkn tulekivist talb ja lihvimiskivi (jn 5B).

Avastatud ja uuritud asulakohad ja matmispai lisavad olulist teavet nöörkeraamika kompleksi kohta. Kui enamik seni Ida-Baltikumi tundud nöörkeraamika asulakohot on segatud varasema või hilisema leiumaterjaliga, siis Narva – Lauga piirkonnas on osa muististest segamata või vaid vähese teiste esiajaloo perioodide leidudega. Muuhulgas osutab see, et elupaikadesse jääenud esemelise materjali ühekülgsus ja ennekõike kivist tööriistade vähesus ei johtu uuringute ulatusest või meetoditest, vaid kajastab tegelikkust (tabel 1). See võib tuleneda nii orgaanilisest materjalist tööriistade enamkasutusest kui ka multifunktionaalsest tulekivist noatüübist, mis asendas teistele kiviajale kompleksidele omaseid erinevaid väikesi kaape- ja lõikeriistu.

Savinõude sarnasust osutab Narva – Lauga piirkonna ühtsele keraamikatraditsioonile ning seob selle laiemalt Eesti, Läti, Ingerimaa, Karjala maakitsuse ja Kagu-Soome alal levinud omanäolise keraamika lokaalrühmaga.

Kahe süvendpõhjalise rõhtpalkelamu jäänused Narva-Jõesuu IIb asulakohal on unikaalsed Läänemere piirkonna nöörkeraamika kompleksides. Kuigi osaliselt maapinda süvendatud põrandasaga hoonepõhju teatakse meile lähimatelt aladelt Rootsist, Poolast, Leedust ja Kaliningradi piirkonnast, on need olnud piüstpostkonstruktsioonis. Ainsad autoritele teadaolevad paralleelid süvendpõhjalistele rõhtpalkelamutele on nöörkeraamika Balanovo rühma alalt Vjatka ja Okaa jõgede vesikonnast Venemaalt.

Erijoontega on samuti Narva-Jõesuu IIb matmispai. Kaksikhauast leitud venekirved ei ole ei Eesti ega vahtutete naaberataladele tüüpilised, neid on seni leitud Läänemere piirkonnast vaid üksikeksemplaridena. Vormilt on need analoogsed Venemaa Volga–Okaa jõgedevahe nöörkeraamika Fatjanovo rühma kirvestele. Samast kulturnirühmest on teada ka parimad paralleelid kaksikhauast leitud väikesele savinõule.

Milline on idapoolsete nöörkeraamika komplekside mõju ja mis on selle põhjused Narva – Lauga piirkonnas, vajab edasisti ja senisest mahukamaid uuringuid.
